

Implementation tricks in the Hungarian Babel module

Abstract. `magyar.ldf`, the Hungarian Babel module was rewritten in the autumn of 2003 to obey most of the Hungarian typographical rules. This article describes some implementation issues, \TeX macro programming hacks and \LaTeX typesetting trickery used in `magyar.ldf`. All features of the new `magyar.ldf` are enumerated, but only those having an interesting implementation are presented in detail. Most of the tricks shown are useful for developing other language modules.

1 The name of the language

Usually a Babel language module has the English name of that language. For example, the German module is called `germanb.ldf`, and not `deutsch.ldf`. The Hungarian module is an exception to this rule, because it has the name `magyar.ldf`, in which “magyar” is the Hungarian adjective meaning Hungarian. A similar exception is `portuges.ldf` for Portuguese. The letter “a” in word “magyar” has to be pronounced as in “blah”, and the consonant “gy” is the same as “d” in due.

The name of a language that a Babel language module (`.ldf` file) defines is specified as an argument of `\LdfInit` in the file. Thus, if `czech.ldf` is renamed to `foo.ldf`, it will have to be loaded with `\usepackage[foo]{babel}`, but still `\selectlanguage{czech}` will have to be used to activate it. This is not the case with `magyar.ldf`, because it detects its loaded filename using the `\CurrentOption` macro set by the `\ProcessOptions` command called from `babel.sty`. So whatever `magyar.ldf` is renamed to, that name has to be passed to `\selectlanguage`.

The only reason why someone wants to rename an `.ldf` file is to load two different versions of it in the same \LaTeX run. This is possible with `magyar.ldf`, but the user should be aware that the control sequences defined by the two copies will interact with each other in an unpredictable way. Experiments have shown that it is possible to load two copies of `magyar.ldf` with different load options (that’s the so-called dual load):

```
\PassOptionsToPackage{frenchspacing=yes}{magyar.ldf}
\PassOptionsToPackage{frenchspacing=no}{hungarian.ldf}
\usepackage[hungarian,magyar]{babel}
```

Despite the name `hungarian.ldf` above, the file `magyar.ldf` gets loaded twice, because Babel translates the language name `hungarian` to file name `magyar.ldf`, and `magyar.ldf` expects options for `\CurrentOption.ldf`, which depends on the language name passed to `\usepackage[...]{babel}`. Since the dual load feature of `magyar.ldf` is experimental, most of the load options cannot be different in the two copies. So the safest way to load two copies is replacing the occurrences of the word `magyar` in the second copy with something else.

The latest `magyar.ldf` (version 1.5) is not part of standard Babel yet, but it is available as part of `MagyarLATEX` (see section 4.1). Most of the typographical rules it tries to obey and most problems it addresses were proposed in [1].

2 What an .ldf file contains

An `.ldf` file is a Babel language module, which contains specific macros for the given language. It is loaded by `babel.sty` in the document preamble, at the time `babel.sty` itself is loaded. The macros defined in `foo.ldf` take effect only after `\selectlanguage{foo}`. The default language is the one specified last in the `\usepackage[...]{babel}` command.

Babel itself contains the standard versions of the `.ldf` files as `tex/generic/babel/*.ldf`. In Babel 3.7 there are 41 of them, most are shorter than 10 kB. The longest files are: the old `magyar.ldf` defining the Hungarian language (25 kB), `frenchb.ldf` defining the French language (23 kB), `spanish.ldf` (21 kB), `bulgarian.ldf` (13 kB), `ukraineb.ldf` defining the Ukrainian language (12 kB), `russianb.ldf` (12 kB) and `greek.ldf` (9 kB). The new version of `magyar.ldf` is much larger than any of these: it is 178 kB long. The big size implies much more functionality, but there are also several features unique to this new `magyar.ldf` – they will be discussed later in this document.

Now let's enumerate common functionality provided by the `.ldf` files, first dealing with features common in most `.ldf` files, then proceeding to features unique to `magyar.ldf`.

2.1 Selecting the hyphenation pattern set

`foo.ldf` must define the control sequence `\l@foo` to be a number (`\newcount`, `\chardef` etc.) representing the hyphenation pattern set to be used for that language. `\selectlanguage{foo}` calls `\language=\l@foo`, which activates the hyphenation patterns for the language “foo”. The patterns were defined with the `\patterns` primitive by the time `iniTEX` was called to generate the format file. The exact filename containing the `\patterns` command is specified in the file `language.dat`. For example, if `language.dat` contains a line “`foot fthyph.tex`”, then `\language=\l@foot` will activate `\patterns` found in `ft hyph.tex`. In that case, `foo.ldf` should contain a line `\let\l@foo\l@foot`. But this line is omitted in most actual `.ldf` files, because the Babel language name and the hyphenation pattern set name is the same (`language.dat` would contain an entry starting with `foo_` in our example). Note that the file `fthyph.tex` is

read by `iniTeX`, not `LATEX`, so the format files have to be re-generated each time `fthyph.tex` is changed.

Three different hyphenation pattern sets have been proposed for the Hungarian language (`huhyph3.tex`, `huhyphc.tex` and `huhyphf.tex`). All of them are maintained by Gyula Mayer ([4]). The most important difference between these lies in the way they hyphenate at subword boundary of compound words. The document author can make `\l@magyar` equal to any of these three by providing the appropriate load option to `magyar.ldf` (see later). The options work by re-defining `\l@magyar` to be one of `\csname l@magyar3\endcsname`, `\l@magyarf` or `\l@magyarc`.

There are two different correct ways to hyphenate compound words in Hungarian. `magyarf` hyphenates the most common foreign compound words of Hungarian text phonetically (e.g. `szink-ron`, meaning `synchronous`), `magyarc` hyphenates them on the subword boundary (e.g. `szin-kron`). `magyar3` is the old version of the hyphenation patterns which hyphenates most composite words phonetically (even non-foreign ones), save a few exceptions listed explicitly. However, in all the three cases, hyphenation of foreign words cannot be perfect, because *all* of them cannot be specified exhaustively in `\patterns`.

`magyar.ldf` can redefine `\l@magyar` to be any of `\l@magyar3`, `\l@magyarf` and `\l@magyarc`, depending on the `hyphenation=` load option. Since some of these pattern sets may be missing from the user's system, `magyar.ldf` falls back to another set with a meaningful warning message. Hyphenation is disabled not by choosing `\language0`, which Babel does, because `\language0` may contain valid patterns for a different language, but `\language255` is chosen, which is very likely to be unused since `LATEX` assigns `\language` numbers from zero.

2.2 Defining captions

`LATEX` generates some words and phrases automatically. For example, `\tableofcontents` should emit the phrase “Table of contents” in the native language. The same applies for `\captions` of figures and tables, and also for `\chapter` titles. Thus Babel expects `foo.ldf` to define a macro `\captionsfoo` containing definitions like `\def\abstractname{Absztrakt}`. These definitions are executed by `\selectlanguage` each time the language is activated. So it is possible to have an English and a Hungarian chapter in a book numbered “Chapter 1” and “2. fejezet”, respectively: `\chapter{foo}\selectlanguage{magyar}\chapter{bar}` `magyar.ldf` has the proper definitions with Hungarian phrases. Some words contain accented letters, which are specified as commands (e.g. `\'a` for “á”) and not 8-bit single characters, so their interpretation doesn't depend on the active input encoding, i.e. the load option of `inputenc.sty`.

2.3 Generating dates

`foo.ldf` should define a macro `\datefoo`, which defines the macro `\today`, which emits a date (specified by the `\year`, `\month`, `\day` registers) correctly on that language. The month name should be printed as a non-abbreviated word. The

definition of `\today` is used by `\@date` invoked in `\maketitle` in the standard document classes.

In addition to defining `\today`, `magyar.ldf` defines the macro `\ondatemagyar`, which defines `\ontoday`, which emits the date with the Hungarian equivalent of English “on” prefix. The Hungarian language has suffixes instead of prefixes, and each suffix has several forms which must follow the vowel harmony of the word it is suffixed to. Thus “on March 15” is emitted as “március 15-én”, but “on March 16” is “március 16-án”, showing that the *-án/-én* suffix has two forms.

2.4 Minimum hyphenation length

TeX doesn’t insert an implicit hyphen into the first `\lefthyphenmin` characters of words, and neither does it in the last `\righthyphenmin` characters. The default L^AT_EX values are `\lefthyphenmin=2` and `\righthyphenmin=3`, which are suitable for the English language. `foo.ldf` can override the default by defining the macro `\foohyphenmins` to be *lr*, two digits specifying the left and the right minimum, respectively.

What `magyar.ldf` does depends on its load options. The default is to follow Hungarian typography: `\def\magyarhyphenmins{22}`.

Nine of the 41 `.ldf` files in Babel 3.7 do only the specializations described so far in this section. 25 languages go a little beyond these, and 7 languages go much beyond. From those 25 + 7 languages that go beyond, `frenchb.ldf` will be compared in detail to `magyar.ldf`, because French and Hungarian share some typographical rules.

2.5 Defining special letters

Many languages have letters missing from the standard OT1 encoding, and some characters are missing even from T1. These should be implemented in `.ldf` files as control sequences. It is a common practice to modify the meaning of an existing letter, for example `czech.ldf` contains `\DeclareTextCompositeCommand{\v}{OT1}{t}{...}`. However, this declaration is contained in `\AtBeginDocument`, so they are in effect even when not the Czech language is active. This should have been avoided.

The correct solution is to use the *extras* facility provided by Babel: `foo.ldf` can have a macro `\extrasfoo`, which is executed each time the language `foo` is activated; and the macro `\noextrasfoo` is executed when the active language is about to change (because of a `\selectlanguage` command or when the end-of-group is reached). It is a common practice in `\extrasfoo` to save the meaning of a macro with `\babel@save`, or a meaning of a count, dimension or skip register with `\babel@savevariable`. The saved meanings will be restored just after `\noextrasfoo` is executed. Babel provides the command `\addto` that can append tokens to the definition of an existing macro. The idiom `\addto\extrasfoo{\babel@save\bar \def\bar{foo-bar}}` is typical, which gives a new meaning to `\bar` while the language `foo` is active.

The macro to be saved for `\DeclareTextCompositeCommand{\v}{OT1}` is `\OT1\v` (with the second backslash part of the control sequence), but assigning the new meaning would be problematic, since `\DeclareTextCompositeCommand` can be used only in the preamble. Thus the correct solution would involve fiddling with undocumented L^AT_EX internals, probably that's why `czech.ldf` contains the problematic workaround involving `\AtBeginDocument`.

Fortunately, the non-English letters in the Hungarian language are only accented vowels (á, é, í, ó, ö, ő, ú, ü and ű), which are all part of the T1 encoding. The letters “ő” and “ű” with the special Hungarian double-acute accent are missing from the Latin-1 encoding (ISO-8859-1), but are part of Latin-2. So authors are encouraged to use `\usepackage[latin2]{inputenc}` with Hungarian.¹ `\usepackage{t1enc}` is also recommended, so T_EX will be able to hyphenate words containing accented letters.

The finest Hungarian books have accents lowered a little bit. This is accomplished for the dieresis accent (¨) by calling the `\umlautlow` command (defined by Babel) in `\extrasmagyar`. No serious attempt is made to make this work for all 3 Hungarian accents, because the technology `\umlautlow` is based on works only for the OT1 encoding (which composes accented letters), but most Hungarian texts use the T1 encoding to have words with accented letters hyphenated.

The lowering of accents is possible using virtual fonts. But T_EX font families come with too many variations and design sizes, so the virtual font generation should be automated. The `\lower@umlaut` macro in `babel.def` lowers accents by forcing their top to be 1.45 ex above the baseline. The `\accent` primitive lowers its accent by `\fontdimen5\font - 1 ex`, so the top of the accent can be forced to 1.45 ex by setting `\fontdimen5\font := \ht0 - 0.45 ex`, where `\ht0` is the height of the accent character (`\char127` in the OT1 encoding). The lowering, in the case of “ü” is as few as 0.43558 pt. Even this few displacement can make a difference: “ü < ü”. The lowering method could be made adaptive by rendering the glyphs involved in high resolution, measuring the number of pixels between the accent and the letter vertically, and then lowering the accent so the distance will be a prescribed constant value.

Neither home users nor professionals use lowered accents in Hungary today, not even with books created with L^AT_EX – the original fonts with the T1 encoding are acceptable enough not to bother changing. TypoTeX Ltd., one of the biggest Hungarian publishing houses that use T_EX has developed the OM fonts in the early 1990s for use with plain T_EX. The OM fonts are a variation of CM fonts with Hungarian accented glyphs added (with lowered accents). However, it is not worth creating `.fd` files for the OM fonts for use with L^AT_EX, because with an equal amount of work new virtual fonts could be created from the EC fonts, that would take advantage of the full T1 character set, and existing, hinted fonts in Type 1 formats (such as the CM-Super fonts).

¹ “ő” and “ű” are the most popular incorrect letters found in Hungarian texts: their presence is caused by software incapable to use Unicode or the Latin-2 encoding. These letters can be seen even on some huge advertisement banners on streets in Hungary. But these texts were not typeset by TeX, of course.

2.6 Hyphenation of long double consonants

However, hyphenating long double consonants is still a little inconvenient. The correct way to hyphenate the double consonant `tty` = `ty+ty` in the word “hattyú” (meaning: swan) is “haty-tyú”. (There is a similar problem in German with words containing “ck”; [5] documents more languages with more exceptions.) The long double consonants involved are: `ccs`, `ddz`, `ddzs`, `ggy`, `nny`, `ssz`, `tty` and `zzs`. `TEX`’s automatic hyphenation algorithm cannot deal with such exceptions, but adding ligatures dealing with the minus inserted by the implicit hyphenation can solve the problem. The simple trick of having `\patterns{t1ty}` and `t + - → ty-2` seems to solve the problem, because it makes “`tty`” hyphenated as “`ty-/ty`”, but it also inserts an extra “y” before the hyphen in “`fut-szalad`”. Normal patterns will also insert an implicit hyphen into “`botcsinálta`”, yielding “`bot-csinálta`”. The ligature program above would incorrectly change that to “`boty-csinálta`”. So a more elaborate set of ligatures have to be constructed, which will detect the context of the hyphen, and insert the “y” only into “`t-ty`”, yielding “`ty-ty`”. Or, equivalently, using `\patterns{tt1y ggy1y}` with context-sensitive ligatures changing “`tt-y`” to “`ty-ty`” and “`gg-y`” to “`gy-gy`” etc.

This solution uses up many character places from the font, and many many extra ligatures are involved. The user should also be informed that any time he wants to see “`t-ty`” (which almost never appears in Hungarian), he has to type `t{}-ty`. All of this can be accomplished using virtual fonts. The author has tried that the concept works by decompiling `aer10.vf` to `aer10.vpl` and modifying the (`LIGTABLE`). However, the automation of the virtual font generation is a work remaining to the future.

The hyphenation of the double two-character consonants “`ggy`” and “`ssz`” are similar to “`tty`”. However, compound words such as “`leggyakoribb`” (meaning: most frequent) and “`vasszekér`” (meaning: iron chariot) should be hyphenated at the subword boundary without adding extra letters: “`leg-gyakoribb`” and “`vas-szekér`”. Extra `\patterns` may be added to disable the insertion of “y” for each important compound word, for example `\patterns{ggy1y .leg1g4yakoribb.}`. This is quite straightforward, because it doesn’t need more ligatures (apart from the context sensitive ligature program changing “`gg-y`” to “`gy-gy`”).

(One might suggest that context-sensitive ligatures can be avoided if “`ty`” is introduced as a new single letter. But this won’t work, because, as step (1): “`t ty`” has to be converted to “`ty ty`” using more than one ligatures, and then step (2): further conversion to “`t ty`” if there is no line break, but `TEX` won’t run its hyphenation algorithm in the middle of ligature processing, between steps (1) and (2).)

The current approach of `magyar.ldf` for handling long double consonants is a compromise. By default, the patterns do not hyphenate those consonants, and the character ‘ is made active (with the standard `Babel` command `\declare@shorthand`), so that, for example ‘`tty` emits `t\nobreak\discretionary{y-}{f}ty\nobreak\hskip\z@skip`. The first `\nobreak` is used to enable automatic

² (`LABEL C t`) (`LIG C - C y`) in the `.pl` file

hyphenation before the ‘`tty`’ construct, and the last `\nobreak` plus the `\hskip` enable hyphenation after the construct. Thus the word typed as `megho’szabbít` will be hyphenated as `meg-hosz-szab-bít`. Similar shorthands are added for the other long consonants. The compromise is that the user has to be aware that he has to insert ‘s manually. A Perl script named `ccs.extract.pl` has been developed, that will collect all occurrences of double consonants in a document so the user can review them and decide about the insertion of ‘ for each different word.

2.7 Table and figure captions

The document class defines the `\@makecaption` macro, which is responsible typesetting a caption of tables and figures. Some `.ldf` files, including `frenchb.ldf` and `magyar.ldf` override the default behaviour. `magyar.ldf` Changes to colon separating the caption heading (e.g. “1. táblázat”, or “Table 1”) from the caption text to a full stop, to match Hungarian typography. Furthermore, the `longcaption=` load option controls what should happen when the caption doesn’t fit in a single line: whether it should be centered and whether there should be a line break after the caption heading.

The `tablecaptions=` and `figurecaptions=` load options control the appearance of the caption heading, by redefining `\fnum@table` and `\fnum@figure`. The default in both cases is to follow Hungarian typography, which requires the form “`<number>. <table name>`” instead of “`<table name> <number>`”.

2.8 Between the section title and the section number

The default definitions of `\@ssect` and `\@sect` separate the section number from the section title with a `\quad`. In Hungarian typography, only an `\enskip` is needed, and a dot has to be inserted after the number. The old version of `magyar.ldf` changed `\@sect` etc., but this caused conflicts with the AMS document classes and several other packages, so that strategy has been given up in the new version of `magyar.ldf`, and dots were moved into the `\numberline` instead, which adds the dot to `\tableofcontents` lines (being careful not to append the dot twice, see dot stripping code in subsection 2.26), and to `\@secntformat`, which adds a dot and the `\enskip` to the titles. AMS document classes do not use `\@secntformat`, so the AMS-specific `\tocsection` and `\tocappendix` commands had to be modified.

`\@numberline` also add a dot after table and figure numbers in the `\listof tables` and `\listoffigures`, but the dot is needed there, too, anyway.

All three TOCs share a common problem related to language changes. Each time the language is changed, `Babel` emits changing commands to the three TOC files, so the time they are re-read, each line comes in its appropriate language. The implementation has a main flaw, however, because the `\write` to the TOC files gets executed when the page is shipped out, and the order of `\writes` on the same page follow the document structure: `\writes` in top insertions precede and bottom insertions follow those in the main text. So when a table or figure is moved to the top of the page, the writing of its TOC entry, together

with the `\selectlanguage` command emitted by Babel is moved away, so `\selectlanguage` commands in the TOC files are reordered, which is wrong. The solution is to emit a `\selectlanguage` command for each TOC entry, so the TOC entries can be freely reordered. `magyar.ldf` implements this solution as a local fix, but it should be fixed generally in the new version of Babel.

2.9 Spacing around punctuation

It is quite easy to add extra space *after* punctuation characters with `\sfcode` (see “space factor” in chapter 13 of [3]). The L^AT_EX `\nonfrenchspacing` command (which is activated by default) assigns a space factor of 3000 to `.`, `?` and `!`, 2000 to `:`, 1500 to `;`, and 1250 to `,`.

However, adding extra space *before* punctuation needs a different approach. Both `frenchb.ldf` and `magyar.ldf` make the characters `:`, `;`, `!` and `?` active with the Babel `\initiate@active@char` interface, and insert unbreakable space in horizontal mode (`\ifhmode`) just before the punctuation character. This feature of `magyar.ldf` can be turned off using the `activespace=` load option, partly because making these four common characters active may lead to incompatibility with other packages, and partly because the extra space before punctuation is very rare in present Hungarian documents. In French typography, about one third of normal space is required before punctuation, and if it is not possible to add that amount with the typesetting technology, one full space should be added. However, in Hungarian, the fallback strategy is to omit the extra space.

The last action the active punctuation character should do is inserting itself, but typing it verbatim into the definition will lead to an infinite loop. For example, `\catcode'?=13 \def?{\kern.1em ?}` will loop infinitely. The solution is using `\string?` in place of the last `?`, so its catcode will be changed to 12 (other). Using `\edef` with `\string` will make the macro a little bit faster, because `\string` will be executed once, at load time.

2.10 Quoted material

In English, text can be quoted using ‘single’ or “double” quotation marks. These can be nested into each other both ways. Hungarian provides three nesting levels: „outer »middle ’inner’ «”. Although the guillemet symbols are missing from the CM fonts with OT1 encoding, this is not a serious problem, since Babel provides them (using the `\l1` relation: `«` and `»`), and Hungarian text should be typeset with the T1 font encoding anyway, to get words with accented characters hyphenated.

`frenchb.ldf` provides the commands `\CyrillicGuillelements` and `\LasyGuillelements` so the user can select the origin of the replacement guillemets. `magyar.ldf` relies on the defaults provided by Babel in the hope that the T1 encoding is used, so replacements are not needed. `magyar.ldf` doesn’t adjust spacing around the quotation symbols, but provides a `\textqq` command that emits quotation with proper nesting and spacing. For example, the three-level sample above can be typed as `\textqq{outer \textqq{middle \textqq{inner}\,}\,}. \textqq`

does English quotation (with two alternating levels) when not the Hungarian language is active.

2.11 List environments

The default spacing, indentation and label item generation of list environments (such as `\begin{itemize}` and `\begin{description}`) are incorrect. The `labelenums=` and `labelitems=` load options control whether labels should be modified to match Hungarian traditions. Five levels of depth are provided for both `\begin{itemize}` and `\begin{enumerate}`. The maximum depth is hard-wired to the L^AT_EX definitions of these environments, so the `\ifnum\@enumdepth>3` test had to be changed to `\expandafter\ifx\csname labelenum\romannumeral\the\@enumdepth\endcsname\relax` (and similarly for `\@itemdepth`).

Although the vertical space the standard document classes leave around lists is too much, and indentation is also incorrect, these problems have not yet been solved in `magyar.ldf`. (`frenchb.ldf` modifies `\itemsep` and other spacing dimensions to match French typographical rules.)

2.12 Modularity using load options

The user can customize `.ldf`s using the language attribute facility provided by Babel. For example, `greek.ldf` contains the declaration `\bbl@declare@ttribute{greek}{polutoniko}{...}`, and if the user loads `greek.ldf` with `\usepackage[greek]{babel}` `\languageattribute{greek}{polutoniko}`, the code in the ... is executed by when `\languageattribute` is called. `\languageattribute`, if present, must be part of the document preamble, and the `.ldf` file must be already loaded.

The fundamental problem of language attributes is that the user can pass only declared keywords, and not arbitrary data to the `.ldf` file, and – since attributes are processed too late – they cannot be used to control which parts of the `.ldf` files should be loaded. That’s why `magyar.ldf` follows a different approach. Options are `<key>=<value>` pairs, which must be declared any time before `magyar.ldf` is loaded. The set of keys are fixed, but values can be arbitrary. It is the responsibility of the macro belonging to the key to verify that the syntax of the value is all right. None of the other `.ldf` files provide load option support this flexible. This option-passing scheme is similar to `keyval.sty`, but `magyar.ldf` doesn’t use `keyval.sty` because of a general design policy to avoid dependencies.

Since `.ldf` file names are the L^AT_EX options to `babel.sty` in the `\usepackage[...]{babel}` line, it is not possible to pass options to the individual `.ldf` files directly. However, L^AT_EX provides the command `\PassOptionsToPackage`, which declares options for a package before the package is loaded. For example, `\PassOptionsToPackage{a=b,c=d}{foo.bar}` appends `a=b,c=d` to the macro `\opt@foo.bar`. `magyar.ldf` examines `\opt@magyar.ldf`, so for example `\PassOptionsToPackage{titles=\enskip}{magyar.ldf}` will force the space in section headings between the section number and the section title to be `\enskip`. (For com-

patibility reasons, `magyar.ldf` also processes the contents of `\magyarOptions` as options. This will be useful when `magyar.ldf` will work with plain `TEX`.)

`TEX` macro wizards may enjoy studying the option parsing code in `magyar.ldf`. The entry point of the routine is the `\processOptions` macro, whose argument is a comma-separated option list of `<key>=<value>` pairs. The routine calls `\processOption{<key>}{<value>}` for each pair found.

```
\def\processOptions#1{\processOptions@a#1,\hfuzz,}
\def\processOptions@a#1,{%
  \if,\noexpand#1,% (1)
  \expandafter\processOptions@a
  \else
    \csname fi\endcsname% (2)
    \processOptions@b#1,=%
  \fi}
\@gobble\iftrue
\def\processOptions@b#1#2=#3,#4\fi{% (3) (4)
  \ifx\relax#4\relax
    \ifx#1\hfuzz% Terminator
      \expandafter\expandafter\expandafter\@gobble% (5)
    \else
      \if,\noexpand#1% OnlySpace
      \else% MissingArg; #2 ends by comma
        \if=\noexpand#1\missingKey#2%
        \else
          \missingVal#1#2\fi
        \fi
      \fi
    \else% Normal
      \processOption{#1#2}{#3}%
    \fi
  \processOptions@a}
\def\missingKey#1,{\errmessage{Key missing for value: #1}}
\def\missingVal#1,{\errmessage{Value (=) missing for option: #1}}
\def\processOption#1#2{\typeout{Got option key=(#1) val=(#2)}}
```

Comments: (1) ignores extra commas, detects them by testing whether `#1` is empty; (2) this is a `\fi` when expanded, but doesn't count as a `\fi` when being skipped over when its surrounding condition is false. The real `\fi` won't be expanded, because it is parsed as the parameter terminator of `\processOptions@b`. (3) needs `#1#2` instead of just `#1`, so `TEX` will ignore space tokens in front of `#1`. As a side effect, when the option begins with `=`, the `=` will be put into `#1`, so `\missingKey` can be reported. (4) There are four different cases in which `\processOptions@b` can be invoked. The exact case is determined by how the macro parameter text separates parameters. The cases are: *Normal case*: `#1#2` is the key, `#3` is the value, `#4` is `=`; *MissingArg case* (`=<value>` is missing, or `<key>` is missing, but `=<value>` is present): `#1#2` is `<key>`, or `=<value>`, `#3`

and #4 are empty; *Terminator case*: #1#2 is \hfuzz,, #3 and #4 are empty; *OnlySpace case*: #1 is ,, #2, #3 and #4 are empty. (5) \@gobble removes the call of \processOptions@a at the end of the macro, so the iteration is finished.

2.13 Default option sets

Since there are 51 load options in the current `magyar.ldf`, the user should not be forced to know all of them. Reasonable defaults are provided instead, so novice users can use the default of defaults (`defaults=over-1.4`), without the need to know that there are options, intermediate users can select one of the 5 defaults, and possibly change a few options they don't like in their preferred default, and only expert users will change options individually.

The number of bytes loaded were measured in a recent version of `magyar.ldf`, totalling 177 353 bytes. Out of that 177 kB, 32 417 bytes were used for initialization and providing the load option support framework, and declaring the options for the 5 defaults. After that, 138 872 bytes were used for implementing features selected by the load options. In the description below, the number of bytes skipped out of the feature bytes are listed. (The smaller the number the more parts of `magyar.ldf` is processed at load time.)

The default sets are:

- `=over-1.4` (not loaded 10 720 bytes) This is the default among the defaults. Its main purpose is to make all documents with the previous version of `magyar.ldf` (1.4) compilable with the new version, to provide emergency bugfixes to the incompatibility problems caused by the old version. It introduces a few essential typographical changes over the new version, which have only little impact on line and page boundaries; but it disables big, eye-catching changes. It makes most of new commands available, but doesn't turn new features on.
- `=compat-1.4` (not loaded 82 890 bytes) Implements a compatibility mode with version 1.4 of `magyar.ldf`. Documents compiled should look the same (but exact match not guaranteed), even if the compatible solution is not correct typographically. It doesn't define new commands such as `\told` or `\emitdate`.
- `=safest` (not loaded 124 679 bytes) Turns off all features, reverts to L^AT_EX and Babel defaults in every respect. It is useful only for debugging purposes: if a document doesn't compile, but it compiles with `defaults=safest`, individual options can be turned on one-by-one to see which of them causes the compatibility problem.
- `=prettiest` (not loaded 1 221 bytes) It turns on all new features, and tries to follow Hungarian typography in the prettiest, most advanced way. It is possible that compatibility problems will arise with other packages, although the author of `magyar.ldf` doesn't know about such problems.
- `=hu-min` (not loaded 1 317 bytes) Follows Hungarian typographical rules as much as possible. (The compliance is not full, of course, because some aspects are not implemented, thus they are not covered by load options, thus they cannot be controlled using defaults.) If typographical rules allow choice (for

example, the first paragraph of a section may or may not be indented), the easiest and most compatible solution is chosen (e.g. accept the indentation defined by the document class).

2.14 Skipping parts of the input file

Since some code parts of `magyar.ldf` can be disabled using load options, it would be wise to skip them completely. The easiest way of skipping part of \TeX code is wrapping it into `\ifnum\MyFeature<1 ... \fi`. But this kind of skipping will consume hash memory for new control sequences skipped over, and it also requires that the skipped part is nested with respect to `\if...s`. `magyar.ldf` defines the following macro that does skipping without these two flaws.

```
\@gobble\iftrue
\def\skiplong#1{\fi
  \bgroup% so ~} would close it
  \catcode\string'^13 \lccode\string'~= \string'^
  \lowercase{\let~\fi}%
  \catcode\string'\14 % comment, save hash memory
  \catcode\string'$14
  \iffalse}
\@gobble\fi
```

After that, code can be skipped with the construct

```
\ifnum\MyFeature<1 \skiplong\fi
...
\@gobble
{~}
```

`\lowercase` is needed in the implementation because `\let~\fi` wouldn't work, because the catcode of `~` is already assigned to be superscript when the definition of `\skiplong` was read.

2.15 Detecting digits for the definite article

`\ref`, `\pageref` and `\cite` generate numbers, which is often prefixed by the definite article in Hungarian. The construct `the \ref{foo}` works fine in English, but the Hungarian definite article has two forms: “a” and “az”. “az” must be used if the following words (as pronounced) starts by a vowel, and “a” must be used for consonants. So there is a strong need for a macro that generates the definite article for numbers automatically. `magyar.ldf` contains the macro `\az`, which prefixes its argument by either `a~` or `az~`. This kind of macro is unique to `magyar.ldf`, other `.ldf` files doesn't seem to contain solutions for similar problems.

Unfortunately, `\az` is not expandable, because it redefines the meaning of several commands before processing its argument. `\az` works by half-expanding its argument (expanding, of course, `\ref`, `\pageref` and `\cite`), ignoring braces and

```
\message{1:\digitthree{} 100:\digitthree{23+}
1000:\digitthree{456}}
```

In this example the macro `\digitthree` expands to “z” if its argument starts with digits of the multiple of 3. `\hbox$` is used as a sentinel to skip everything after the last digit has been found. The sentinel must not be present in the parameter itself. `\hbox$` makes no sense in \TeX , so it is quite reasonable to assume that the parameter doesn’t contain this. `magyar.ldf` uses `\hfuzz` and `\vfuzz` when only a single token is allowed, because these two unexpandable tokens are quite rare. The three consecutive slashes in the example are three sentinels, so `\digitthree@` has always enough arguments.

The test doesn’t work if the parameter of `\digitthree` contains braces, for example `\digitthree{1{2x}}` would look for the undefined control sequence `\digitthree@x`.

In the example the `\csname` trick was used to avoid `\expandafter` in the nested `\ifs`.

See the definition of `@@magyar@az@set` in `magyar.ldf` for using three multi-character sentines in the same macro.

2.17 The definite article in front of roman numbers

`\az` in `magyar.ldf` (see in subsection 2.15) works differently for `\az{x}` and `\az{\romannumeral 10}`, but how should it distinguish when `\romannumeral` has already been expanded by the time `\az` is called? There is no general solution to the problem, but `magyar.ldf` addresses the case when `\az{\ref{my-part}}` is called, having label `my-part` pointing to a `\part`, when `\def\thepart{@Roman \c@part}` is active. (This is so with the standard `book.cls`). `\ref` gets the part number from the `\newlabel{my-part}{x}{42}` command written to the `.aux` in the previous run of \LaTeX . `\label`, which has emitted this `\newlabel` has already expanded `\romannumeral` in the previous run, a long time before our `\ref` is called.

To make the definite article work in this special case, `magyar.ldf` redefines `\label` so it writes `\hunnewlabel` to the `.aux` file in addition to `\newlabel`. The arguments of `\hunnewlabel` are pre-expanded when `\let\romannumeral\number` is in effect. This solution also works when `\pageref` refers to a roman page number. Making the page number expanded in the right time is rather tricky. \LaTeX `\protected@write` says `\let\thepage\relax`, which prevents expansion in the following `\edef`, so `\thepage` is expanded only when the page is shipped out, and `\c@page` contains the right page number. What we want is half-expanding `\thepage`, so it gets expanded to `@roman\c@page`, and `@roman` gets expanded to `\number (!)`, but the expansion of `\number\c@page` is postponed until the page is shipped out. This can be accomplished by defining `\def\romannumeral{noexpand\number}` before calling `\protected@write`. Actually, `magyar.ldf` itself expands the page number once, so three `noexpands` are needed in front of `\number`.

Redefining `\label` (so it emits `\hunnewlabel`) also raises a problem. Some packages loaded later might also override `\label`, for example `hyperref.sty` loads `nameref.sty` `\AtBeginDocument`, which overrides `\label`. `magyar.ldf` recognises the new definition when the Hungarian language is activated – which is done after the `\AtBeginDocument` hooks are run (see subsection 2.21), so `\hunnewlabel` works fine with `hyperref.sty`.

2.18 Removing all braces

Removing all braces from a token list is required by `\az` command (that inserts the *a/az* definite article). `\az` can find the first letter of its argument more easily if the argument doesn't contain braces.

```
\@gobble\iftrue
\def\removebraces@stop#1#2\fi{#1}%
\def\removebraces#1{%
  \ifx\hfuzz#1\removebraces@stop\fi
  \expandafter\removebraces\expandafter{%
    \ifcat{\noexpand#1\hfuzz\iffalse}\fi\expandafter
    \removebraces\else\hfuzz}\removebraces@nob{#1}\fi}
\def\removebraces@nob#1#2{#2% #2 is \fi
  \ifx\hfuzz#1\hfuzz\expandafter\@firstoftwo
    \expandafter\removebraces\fi\removebraces@nobone#1}
\def\removebraces@nobone#1{\noexpand#1\removebraces}
\message{R:\removebraces {{foo}}{b}{{{a\fi}}}{r}}\hfuzz;}
```

The `\removebraces` macro defined above removes all braces and spaces (recursively) from the tokens following it, till the first `\hfuzz`. The tokens may not contain a `\hfuzz` inside braces, but they may contain expandable material, even with unbalanced conditionals, because those are left unexpanded by the `\noexpand` in `\removebraces@nobone`. The most important trick here is the `\ifcat{\noexpand#1}` construct, which is true if `#1` starts with a brace, and yields `#1` with its first brace stripped. `\iffalse}\fi` is needed so that the macro definition is nested with respect to braces. The usage of `\@firstoftwo` is also worth mentioning: it is used to change the `\removebraces@nobone` token following the `\if` to `\removebraces`.

2.19 Changing `\catcodes` safely

`\makeatletter` is equivalent to `\catcode 64 12` on ASCII systems, which changes the category code of character having code 64 to 12 (letter). It is possible to specify the character `@` without knowing its character code: `\catcode'@12`. Wherever `TEX` looks for a number (after `\catcode`, `\romannumeral`, `\number` and `\ifnum` etc.), it accepts a decimal number, an octal number prefixed by `'`, a hexadecimal number with digits `0–9A–F` prefixed by `"`, an internal counter (such as `\linepenalty`), a `\count` register (such as `\count42` or `\@listdepth`) or a

character prefixed by ‘. The character can be specified as a character token, or as a single-character control sequence. It is wise to specify {, }, % and space as \{, \}, \% and _, respectively, so the whole construct would be properly nested with respect to braces, and the % and space tokens won’t be ignored.

However, many Babel language modules (.ldf files) make the character ‘ active (i.e. \catcode 13), so the definition of ‘ gets expanded in \catcode‘@12. The expansion can be prevented by \noexpand, but \noexpand‘ yields ‘_13, which is wrong, because ‘_12 is needed, and moreover, will be expanded in the second run, because T_EX is looking for a number. Fortunately, \string‘ solves the problem, because \string changes the \catcode of the following character token to 12 (other) or 10 (space) (and, if a control sequence follows, \string converts it to a series of character tokens with \catcode other or space). Thus, the most perfect definition of \makeatletter is \catcode\string‘\@11_, which doesn’t rely on the previous \catcode of ‘ or @. The space at the end of the definition is needed so T_EX knows that the number 11 won’t be followed by subsequent digits. Of course, the definition works only when the characters catcodestring have \catcode letter, \ is an escape character (\catcode 0), and space is a space (\catcode 10). These are reasonable assumptions, because none of standard L^AT_EX packages change them.

The L^AT_EX kernel’s definition of \makeatletter is \catcode‘\@11\relax, having \relax instead of space, which is equally good to mark the end of a number. This definition doesn’t need \string, because by the time it is read, the \catcode of ‘ is guaranteed to be 12 (other).

magyar.ldf saves the \catcode of ‘ ! & + - = | ; : ’ " ? / in the beginning, changes them to other, and restores them just before \endinput. This is needed in case some other .ldfs have been loaded (e.g. \usepackage[french, magyar]{babel}), which have redefined some \catcodes. For example, french.ldf activates ! ? ; :.

It is also a good idea not to change \catcodes until \begin{document} (not even in \AtBeginDocument), because other packages to be loaded may depend on the old, unchanged \catcodes. Babel, unfortunately, activates a character immediately when a shorthand is defined in a .ldf file, so this can raise strange compatibility issues – part of which can be resolved by loading most of the packages before Babel. magyar.ldf solves the problem by not touching the \catcode of its own shorthands at the time of definition, but calls \bbl@activate in \extrasmagyar, and \bbl@deactivate in \noextrasmagyar. This is a local and temporary solution only, future versions of Babel are expected to postpone character activation as far as \@preamblecmds (see also in subsection 2.21).

2.20 Shorthands

A shorthand is an active character defined by an .ldf file with the \declare@shorthand command provided by Babel. In this sense, all active punctuation characters (see in subsection 2.9) are shorthands. But the most important shorthand in magyar.ldf is ‘_13. (Most .ldf files choose that character to be main

shorthand, but some files such as `germanb.ldf` choose "13.) The use of Hungarian shorthands can be disabled by the `active=` load option, and the shorthand character is controlled by the `activeprefix=` load option, with the default being '13. `magyar.ldf` even provides the `\shu` command, which is a longer version of '13, but without the possibly dangerous `\catcode` change. Each shorthand is an active character, which raises compatibility problems (see more in subsection 2.19). `magyar.ldf` tries as hard as possible avoid problems, but all effort is vanity if another `.ldf` file is loaded which activates the same shorthand the unsafe default way.

For the user a shorthand is a control sequence without a backslash. So a shorthand is a command that can be typed and read quickly. `germanb.sty` provides "a to be equivalent to \a, saving a keypress for every accented German letter. `magyar.ldf` doesn't provide this save, because the letters o and u have 3 accented forms, and introducing different letters for them would lead to confusion. Hungarian L^AT_EX authors are encouraged to use the `latin2` encoding to type accented letters as a single character.

But the shorthand does an important job concerning (unaccented) long double consonants, for example 'tty is an abbreviation for `t\nobreak\discretionary{y-}{-}{ty}\nobreak\hskip\z@skip`. See the reason why this is needed in subsection 2.6. It should be noted that shorthands are implemented as T_EX macros, so 't{t}ty and 'tty are treated equivalently.

The shorthand functionality of `magyar.ldf` for non-letters are inspired by `ukraineb.ldf`, which contains many of those. '=' and '-' stand for a hyphen that separates words, so both words are automatically hyphenated by T_EX (the implementation is `\leavevmode\nobreak-\hskip\z@skip`); '- in math mode stands for a space character following a delimiter (`\mskip2.4mu plus3.6mu minus1.8mu`) that will magically be exactly as wide as if a space was inserted outside math mode, because the implicit `\mskip0.6mu` after the delimiter is already subtracted; '-- emits \,--\,, to be used between author names in Hungarian bibliographies; '| emits a hyphen that will be repeated in the beginning of the next line if the line is broken there (`\leavevmode\nobreak-\discretionary{-}{-}{-}\nobreak\hskip\z@skip`), to be used with words having (e.g. "nátrium-klorid") important hyphens; '_' inserts a discretionary hyphen with automatic hyphenation enabled at both sides; '< inserts a french opening guillemot even if the ligature << is missing from the current font; '> inserts its pair; '"' is equivalent to `\allowbreak` with hyphenation enabled at both sides (implementation: `\hskip\z@skip`); '~ inserts a hyphen that doesn't form ligatures when repeated (implementation: `\textormath{\leavevmode\hbox{-}}{-}`).

2.21 Inserting code to \@preamblecmds

Babel calls `\selectlanguage` to set the default language `\AtBeginDocument`, which is too early in general. Suppose that the default language redefines some `\catcodes` to be used with active characters. All packages that are loaded after the default language is activated, will contain characters with unexpected and invalid catcodes. For example, if `hyperref.sty` is loaded after `magyar.ldf`, the

`\AtBeginDocument` entries of `hyperref.sty` contain `\RequirePackage{nameref}`, which is executed *after* the entry `\selectlanguage{magyar}` of `babel.sty`, so `nameref.sty` will be loaded with wrong catcodes, so it won't work.

The solution to this is to postpone the activation of the default language after the `\AtBeginDocument` hooks. This is accomplished by `magyar.ldf` by appending to `\@preamblecmds`, which is executed by the L^AT_EX kernel in `\document` after the `\AtBeginDocument` hooks. But what about the call to `\selectlanguage` call inserted to `\AtBeginDocument` by `babel.def`? It becomes a no-op, fortunately, because `magyar.ldf` modifies `\selectlanguage` to do nothing if the name of the language (`\language`) hasn't changed – and exactly this is the case when activating the default language. Of course, `\@preamblecmds` has to force the change even with unchanged `\language`, so it calls `\select@language` (notice the at-sign).

So `magyar.ldf` adds `\select@language` to `\@preamblecmds`, and it also runs `\pagestyle{headings}` for the relevant document classes, so `\ps@headings` will be executed once more, and the Hungarian version of the headings, as defined by `magyar.ldf` will get a chance to be installed.

2.22 Displaying theorem titles

In English, theorem titles are displayed as “Theorem 1”, but Hungarian requires “1. tétel.”. To apply the changes, the `\@begintheorem` and `\@opargbegintheorem` macros are redefined each time the Hungarian language is activated. However, if `theorem.sty` or `ntheorem.sty` is loaded, the changes have to be embedded into a theorem style. The chosen name for the style is `magyar-plain`. It is activated by default when `magyar.ldf` is loaded, so theorem titles will come out right unless the user calls `\theoremstyle`. When `amsthm.sty` is loaded, `magyar.ldf` redefines the macros `\thmhead` and `\swappedhead` so both of them will emit the title properly.

2.23 Extra symbols \paragraph titles and description items

Hungarian typography requires a separator character different from a dot to be inserted after the `\paragraph` title, so the English paragraph start “**title** text” should be something like “**title** ♦ text”. `magyar.ldf` provides several pre-defined title separation symbols, selected by the load option `postpara=`; `postsubpara=` controls `\subparagraphs` and `postdescription=` controls `\items` in the description environment.

`magyar.ldf` redefines `\paragraph` in a really ugly way when `postpara=` is active, so that no extra horizontal space is inserted after the title, but the title ends by the separation symbol. The default definition of `\paragraph` is based on `\@startsection`, whose #5 is a negative skip, which means a positive horizontal skip after the title. This is changed to `-1 sp` by `magyar.ldf` to avoid the skip, and an optional argument is always passed to the original `\paragraph` so the title will be typeset with the separator.

2.24 Forcing indentation after section titles

Hungarian typography allows the first paragraph following the section title to be either indented or unindented, so `magyar.ldf` provides the load option `afterindent=` to control this. L^AT_EX calculates the value of the boolean variable `\if@afterindent` from the signedness of a parameter of `\@startsection`, and later uses that boolean to insert or omit the indentation. The value of the boolean is forced to true by `magyar.ldf` with the simple definition `\let\@afterindent false\@afterindenttrue`.

2.25 The decimal comma

The dot character is defined as *ordinary* by default, so decimal real numbers can be typed simply as `-12.34`. In Hungarian, however, the decimal point is denoted by a comma instead of a dot, but typing `$-12,34$` yields “–12,34” with too much space after the comma, because the comma is punctuation rather than an ordinary character. `$-12{,}34$` yields “–12,34”, which is correct, but `magyar.ldf` provides two mechanism to save the two keypresses of the curly braces around the comma. The `\HuComma` macro below inserts an ordinary comma if it is followed by a digit, and an operator comma otherwise:

```
\edef\hucomma@lowa#1#2 #3#4 #5#6\hfuzz{%
  \noexpand\ifnum9<1#5 \noexpand\if#1t\noexpand\if#3c% (1)
  \noexpand\mathord\noexpand\fi\noexpand\fi\noexpand\fi\mathchar
  \ifnum\mathcode'',"8000 "613B \else\the\mathcode', \space\fi}
\def\hucomma@lowb{\expandafter\hucomma@lowa
  \meaning\reserved@a/ / \hfuzz}%
\DeclareRobustCommand\HuComma
  {\futurelet\reserved@a\hucomma@lowb}
```

These macros were inspired by the solution proposed to the comma problem by Donald Aresenau. In line (1) `\hucomma@lowa` tests whether the `\meaning` of the following character is “the character <digit>”. A `\meaning` is always at least three words, but it may be more (e.g. “math shift character \$”). Only “the character” starts with letters “t” and “c”. `\edef` is needed above so the `\mathchar` emitted doesn’t depend on `\mathcode` changes after the definition of `\HuComma`.

Then the comma character can be redefined to be `\HuComma`:

```
\expandafter\addto\csname \expandafter\ifx\csname mathoptions@on
  \endcsname\relax \check@mathfonts\else mathoptions@on\fi
  \endcsname{\catcode',12 \mathcode',"8000
  \begingroup\lccode'~',\lowercase{\endgroup\def~}{\HuComma}}
```

With these definitions, the formula “ $F_i(x, y) = y^i + 1, 3x$, $x, y \in A$, $i = 1, 2, 3, \dots$ ” can be typed simply as `$F_{i}(x,y)=y^i+1,3x,\ x,y \in A,\ i=1,\ 2,\ 3,\ \ldots$`, if `_` is breakable (such as in `nath.sty`).

The definitions are appended to `\mathoptions@on` when `nath.sty` is loaded, and `\check@mathfonts` when `nath.sty` is missing. The appropriate macro is run

just before `\everymath` by L^AT_EX. Redefining the `\catcode` and `\mathcode` this way ensures that the proper comma is used inside math mode – unless the whole math formula is a macro argument with already assigned `\catcodes`. Also not the smart use of `\begingroup`, `\lccode`, `\lowercase` and `\endgroup` to modify the active meaning of a character without actually activating it. `\catcode‘,13` before `\def`, wouldn’t help here anyway if the whole construct is embedded into a macro definition, because `\catcode` wouldn’t be able to change an already assigned catcode.

`frenchb.lfd` provides the commands `\DecimalMathComma` and `\StandardMathComma` to change the `\mathcode` of the comma. However, the smart comma based on `\HuComma` act correctly without the user needing to be aware of curly braces or redefinitions.

The solution above can be activated with the loading option `mathhucomma=fix`. An alternative approach doesn’t change `\mathcodes`, but introduces a special math mode in which the dot appears as a comma only when the Hungarian language is active. Thus the printout of `\MathReal{-12.34}` depends on the current Babel language. The definition of `\MathReal` in `magyar.lfd` is similar to:

```
\def\mathreal@lowa#1{\ensuremath{\mathreal@lowb#1%
  \@gobble.}}
\def\mathreal@lowb#1.{%
  #1\@secondoftwo\@gobble% (1)
  {\mathchar"013B \mathreal@lowb}}% comma
\DeclareRobustCommand\MathReal{\ensuremath}%
{\catcode‘\ 11\relax\addto\extrasmagyar{%
\babel@save\MathReal %
\let\MathReal \mathreal@lowa}}
```

The argument of `\MathReal` must contain the dot to be changed literally, outside braces. There is a little macro wizardry in the implementation that stops calling `\mathreal@lowb` infinitely. `\mathreal@lowa` terminates its argument by a sentinel `\@gobble.`, so `#1` of `\mathreal@lowb` will end by `\@gobble`, which will gobble `\@secondoftwo`, so the `\@gobble` in line (1) will take effect, which stops the recursion.

`\MathReal` is going to be extended in the future so it will handle physical units following the number properly, and it will also insert thin spaces after each three digits. This feature has already been implemented in `frenchb.lfd`.

2.26 Parsing dates

There are many correct ways to write dates in Hungarian, and `magyar.lfd` provides the `\emitdate` command that can generate all of these formats. But doing the reverse is a little more interesting. Let’s suppose we have a Gregorian date consisting of a year (4 or 2 digits), a month (a number or a name) and a day-of-month in some standard format. We need the command `\parsedate` that will detect the format, split the date into fields, and call `\fixdate`:

```

\def\fixdate#1#2#3{%
  \@tempcnta#1 \ifnum#1<50 \advance\@tempcnta2000 \fi
  \ifnum\@tempcnta<100 \advance\@tempcnta1900 \fi
  \typeout{found year=(\@tempcnta) month=(#2) day=(#3)}
}

```

Many dates have an optional dot at the end. Since that dot doesn't carry useful information, we should remove it first. The `\stripdot` command defined below expands to its argument with the trailing dot removed. `\stripdot` works only if the argument doesn't contain the token `\relax`. `\relax` is not special, any other token would have worked.

```

\def\stripdot#1{\expandafter\stripdot@lowb\stripdot@lowa
  #1\relax.\relax}%
\def\stripdot@lowa#1.\relax{#1\relax}%
\def\stripdot@lowb#1\relax#2\relax{#1}%

```

The definition of `\parsedate` is the following:

```

\def\parsedate#1{%
  \begingroup
    \def\today{\the\year-\the\month-\the\day}% ISO format
    \let\protect\string
    \let'\@firstofone% remove accents from Hungarian month names
    \let~\space% change '2003.~okt' to '2003. okt'
    \edef\re@b{\def\noexpand\re@b{#1}}%
  \expandafter\endgroup\re@b
  \edef\re@b{\expandafter\stripdot\expandafter{\re@b}}%
  \let\re@a\@empty \expandafter\parsedate@a\re@b!--!\hfuzz
  \ifx\re@a\@empty \expandafter\parsedate@f\re@b!//:!\hfuzz \fi
  \ifx\re@a\@empty \expandafter\parsedate@b\re@b!//!\hfuzz \fi
  \ifx\re@a\@empty \expandafter\parsedate@c\re@b!..!\hfuzz \fi
  \ifx\re@a\@empty \expandafter\parsedate@d\re@b!. xyz !\hfuzz \fi
  \ifx\re@a\@empty \expandafter\parsedate@e\re@b!xyz , !\hfuzz \fi
  \ifx\re@a\@empty \errmessage{Unrecognised date: \re@b}%
  \else \re@a% call \fixdate
  \fi}

```

`\parsedate` first does some generic cleanup, and puts the resulting date into `\re@b`. `\endgroup` cancels the redefinition of `\today` etc., but `\re@b` is expanded first, which defines itself, so the value of `\re@b` will be retained after `\endgroup`. After that, the trailing dot is stripped, and then various `\parsedate@...` commands are run. If one command recognises the date format, it puts a call to `\fixdate` into `\re@a`, which will be called at the end of `\parsedate`. The strange strings like `!//:!\hfuzz` are sentinels.

The idiom `\expandafter\endgroup\re@b` is an important trick to expand a macro before the current group completes (and changes are undone). This extra macro usually contains definitions of other control sequences whose meaning are about to be retained after the end of the group. An alternative would be to

inject such a definition using `\aftergroup`, but it only accepts a single token, so it would be very painful to make a macro definition with spaces and braces survive this way.

The individual `\parsedate@...` commands are the following:

```
\def\parsedate@a#1-#2-#3!#4\hfuzz{% ISO date: YYYY-MM-DD
\ifx\hfuzz#4\hfuzz\else \ifnum1<1\string#1\relax
\ifnum1<1\string#2\relax \ifnum1<1\string#3\relax
\def\re@a{\fixdate{#1}{#2}{#3}}%
\fi\fi\fi\fi}

\def\parsedate@b#1/#2/#3!#4\hfuzz{% LaTeX date: YYYY/MM/DD
\ifx\hfuzz#4\hfuzz\else \ifnum1<1\string#1\relax
\ifnum1<1\string#2\relax \ifnum1<1\string#3\relax
\def\re@a{\fixdate{#1}{#2}{#3}}%
\fi\fi\fi\fi}

This implementation of date parsing isn't error-proof. If something weird is passed to `\parsedate`, it may produce surprising \TeX errors. However, `\parse date` can distinguish between different formats of correct input.

2.27 Setting up french spacing

Hungarian typography requires `\frenchspacing` turned on, but most \LaTeX users don't seem to follow this requirement. Babel provides the `\bbl@frenchspacing` command, which turns french spacing on if it was off. The `frenchspacing=load` option of `magyar.ldf` controls how Hungarian text should behave. For the sake of symmetry, `magyar.ldf` provides `\@@magyar@antifrenchspacing`, which – contrary to the typographical requirement – turns french spacing off:

```
\def\@@magyar@antifrenchspacing{%
  \ifnum\the\sfcode'\.=\@m
    \nonfrenchspacing
    \let\@@magyar@nonfrenchspacing\frenchspacing
  \else \let\@@magyar@nonfrenchspacing\relax \fi}
\let\@@magyar@nonantifrenchspacing\frenchspacing
\addto\extrasmagyar{\@@magyar@antifrenchspacing}
\addto\noextrasmagyar{\@@magyar@nonantifrenchspacing}
```

2.28 varioref.sty fixes

The `magyar` load option of `varioref.sty` (2001/09/04 v1.3c) is buggy, because it uses the never defined `\aza` command for adding definite articles, and it also calls `\AtBeginDocument` too late, producing a \LaTeX error each time the Hungarian language is activated. `magyar.ldf` contains the correct definitions for the language-specific text reference macros, such as `\reftextlabelrange`, and also contains ugly fixup code to remove the wrong macros inserted by `varioref.sty`. A patch has been sent recently to the author of `varioref.sty`.

Some of these text reference macros use the `\az` and the `\told` commands defined by `magyar.ldf`.

2.29 Removing the full stop after section titles in AMS classes

AMS document classes always append a full stop after section titles, which is strictly forbidden in Hungarian typography. The solution is to remove the tokens `\@addpunct.` from the definition of `\@sect` (and also from `\NR@sect` in case `nameref.sty` has also been loaded). But this simple idea is quite complicated to program, and the result is ugly:

```

\expandafter\amssect@fixa\@sect[] [] [] [] [] [] []%
\global\@nobreaktrue\@xsect\hfuzz\@sect
\expandafter\amssect@fixa\@sect[] [] [] [] [] [] []%
\global\@nobreaktrue\@xsect\hfuzz\NR@sect% with nameref.sty
\long\def\amssect@fixa#1\global\@nobreaktrue\@xsect#2\hfuzz#3{%
\ifx\hfuzz#2\hfuzz\else\amssect@fixb#3\fi}% fix if found
\def\amssect@fixb#1{% #1 is \@sect or \NR@sect
\expandafter\let\csname amssect@saved\string#1\endcsname#1%
\edef#1{\noexpand\expandafter\noexpand\amssect@low\expandafter
\noexpand\csname amssect@saved\string#1\endcsname}%
\let\@svsechd\@empty% prevent Undefined \cs
\long\def\amssect@low##1\global\@nobreaktrue{##1%
\expandafter\def\expandafter\@svsechd\expandafter{%
\expandafter\let\expandafter\@addpunct\expandafter\@gobble
\@svsechd}%
\global\@nobreaktrue}}

```

This detects AMS classes by the presence of `\global\@nobreaktrue\@xsect` in the definition of `\@sect`, and adds code just before `\@xsect`. The code added prepends `\let\@addpunct\@gobble` to the definition of `\@svsechd`. `\@svsechd` is later called by `\@xsect`, which calls `\@addpunct`, but by that time `\@addpunct` is a no-op. The application of this fix is controlled by the `amspostsectiondot=load` option.

2.30 Reduced math skips

Investigations in [1] have shown that the following settings produce the desired space in Hungarian math mode:

```

\thickmuskip 4mu plus 2mu minus4mu % LaTeX: 5mu plus5mu
\medmuskip 2mu plus1.5mu minus2mu % LaTeX: 4mu plus2mu minus4mu
\thinmuskip 3mu % LaTeX: ditto

```

Notice that `\medmuskip < \thinmuskip`. These settings can be selected in `magyar.ldf` with the load option `mathmuskip=`. The difference between the original and the reduced spacing:

$$a + b - c/d * y \circ x = z \qquad a + b - c/d * y \circ x = z$$

2.31 Breaking a long inline math formula

Hungarian typography requires that a binary relation or operator (e.g. in $1 + 2 = 3 + 4$) must be repeated in the next line if an inline math formula is broken there. This can be accomplished for the equation sign by substituting `=\nobreak\discretionary{}{\hbox{\(=\)}}{}{}` for `=` in math formulas. The long inline formula delimiters `\(` and `\)` are used because the catcode of the `$`

would be wrong if `nath.sty` was loaded after `magyar.ldf`. `\nobreak` is necessary, so \TeX itself won't break the line after the “=”.

The `mathbrk=` load option of `magyar.ldf` controls whether the operators and relations should be redefined. If so, the operators `+`, `-`, `*` (as well as 37 operators available as control sequences) and the relations `<`, `>`, `=`, `:` (as well as 43 relations available as control sequences) are modified so they get repeated at the beginning of the line. The `\cdot` and the `\slash` operators are also modified, because Hungarian typography disallows breaking the line around them.

2.32 Restarting footnote numbering on each page

Although `\usepackage[perpage]{footmisc}` and `footnpag.sty` provide these features, `magyar.ldf` allows normal arabic footnote and page-restarting asterisk-footnotes to be intermixed. It is common in Hungarian article collections to have the notes of the author numbered in arabic (by `\footnote`), and the footnotes of the editor added with asterisks (by `\editorfootnote`). The first four editorial footnotes on a page are marked with `*`, `**`, `***`, and `†`. `magyar.ldf` also inserts proper additional space between the footnote mark and the footnote text, and the footnote facility is fully customizable with the `\footnotestyle` command.

The basic idea behind the implementation of pagewise numbering is creating a `\label` for each footnote, and whenever the `\pageref` for that label shows a different page, resetting the counter to zero. This clobbering can be automated by abusing the `\cl@footnote` hook. Each time `\stepcounter` advances a counter, the corresponding `\cl@...` hook is called, which usually resets other counters (for example, advancing the chapter counter resets the section counter). But arbitrary code can be executed after the automatic `\stepcounter{footnote}` by appending that code to the macro `\cl@footnote`.

The famous problem of creating a macro that will expand to n asterisks is proposed in chapter D of the \TeX book ([3]). David Kastrup has provided a brilliant solution to the problem in [2]: `\expandafter\mtostar\romannumeral\number n000A`, where `\mtostar` transforms `ms` to asterisks: `\def\mtostar#1{\if#1m*\expandafter\mtostar\fi}`. This solution is used in `magyar.ldf`.

`magyar.ldf` provides the following command to insert footnotes into section titles, so neither the table of contents, nor the page headings will be affected:

```
\def\headingfootnote{%
  \ifx\protect@typeset@protect\expandafter\footnote
  \else\expandafter@gobble\fi
```

2.33 Class-specific modifications

`magyar.ldf` does some modifications based on the current document class (using the `\@ifclassloaded LATEX` command). Only the standard classes `article.cls`, `report.cls`, `book.cls` and `letter.cls` are supported now. The visual appearance of the `\part` and `\chapter` commands are changed, and the page headers are also modified. For `book.cls`, part numbering is spelled out, so “Part 1” becomes “Első rész”

(meaning “Part One”) if the load option `partnumber=Huordinal` is active. The command `\ps@headings` has to be executed again to install its changed heading macros. This is called after `\AtBeginDocument` hooks from `\@preamblecmds`, after the default language has been activated (see in subsection 2.21).

The typographically correct customization of `letter.cls` is under development.

2.34 Spelling out numerals and ordinals

The `\@hunumeral` and `\@huordinal` macros defined in `magyar.ldf` can spell out integers between -9999 and 9999 . `\@Hunumeral` and `\@Huordinal` are the capitalized versions of these macros. For example, `\@huordinal{2004}` yields “kétezer-negyedik” (meaning: two thousand and fourth), and `\@Hunumeral{2004}` yields “Kétezer-négy” (meaning: Two thousand and four). All these macros are fully expandable, so they can be used for `\part` numbering: `\def\thepart{\@Huordinal\c@part}`, or more simply: `\def\thepart{\Huordinal{part}}`.

The most important implementation issue is the method to retrieve the last digit of a number in an expandable construct. If the number is between 0 and 9999, the following macro solves the problem:

```
\def\LastDigitOf#1{\expandafter\lastdigit@a\number#1;}%
\def\lastdigit@a#1;{% #1 in 0..9999
  \ifnum#1<10 #1\else\ifnum#1<100 \lastdigit@b00#1%
  \else\ifnum#1<1000 \lastdigit@b0#1\else\lastdigit@b#1\fi
\def\lastdigit@b#1#2#3#4{#4}
```

2.35 Suffix generation

The Hungarian language doesn’t have prepositions for representing relations in space and time, but it has suffixes to be appended to the end of the word for the same purpose. For example, an English maths text might contain “It follows from (1)”, in which “from (1)” can be typed as `\from{\ref{eq1}}`. The L^AT_EX referencing scheme guarantees that the text above will come out right, even if the order of equations is changed in the document. But in Hungarian, the suffix standing in place of “from” has two forms: *-ból/-ből*, depending on the vowel harmony of the pronunciation of `\ref{eq1}`. So there is a need for automatic suffix generation. `magyar.ldf` provides the command `\told`, with which the Hungarian version of “from (1)” can be typed as `\told{\ref{eq1}}+ból{}`, which will generate “(1)-ból”, “(2)-ből”, but “(3)-ból”.

`\told` knows about 20 different suffixes, and $4 \cdot 20$ suffix combinations (such as `\told3+adik+ra{}`, meaning: to the third). Only the last number is considered of references containing multiple numbers. Roman numbers are recognised properly in references with the help of `\hunnewlabel` (see in subsection 2.17) – this is implemented similarly as with `\az`. Suffix generation is supported only for integers and Hungarian document structure names (see in subsection 3.2), because writing a generic suffix generator that doesn’t need a database is quite

a difficult task, and definitely won't give Hungarian L^AT_EX users much more comfort beyond the current `\told` implementation.

Although most Hungarian suffixes has 1, 2 or 3 forms,³ numbers can be classified into 23 paradigm classes, so that the paradigm class uniquely determines the correct form of all known suffixes. The reason why there are so many classes, is because the letter “v” of the *-val/-vel* suffix must be also changed to the last letter of the number if that letter is a consonant. So, essentially each final digit has a class, and there are classes for the powers of 10, and some of the numbers 20, 30 ... 90 also have their own classes. Adding up all these, the final number 23 is reasonable. So it is true that the suffix of a number depends on the last nonzero digit, and the number of trailing zeroes.

The implementation of `\told` is suprisingly long and ugly, full of recursive macros that parse the input; and doesn't contain bright new ideas not found elsewhere in `magyar.ldf`. The curious T_EX hacker should study `\az` instead, because it is shorter and its trick density is much higher.

2.36 Warning messages

`magyar.ldf` has a unique feature that it displays warning messages (called “suggestions”) at load time to notify the user that they are using `magyar.ldf` in a possibly wrong way. If they are not disabled by the `suggestions=` load option, are following suggestions displayed on the terminal during the `\AtBeginDocument` hook:

- the user forgot to load `\usepackage{t1enc}` – so words with accented letters won't be hyphenated automatically;
- the user forgot to load `\usepackage[latin2]{inputenc}`, or the input encoding chosen is not `latin2`, `cp1250` or `utf8` – so there is a high chance that accented characters disappear or come out wrong;
- the Hungarian hyphenation patterns requested were not found – `magyar.ldf` tries using the other 2 possible Hungarian patterns, if they are available;
- `\def\magyarOptions` or `\PassOptionsToPackage{...}{magyar.ldf}` was specified too late – late options can be detected, but they have no effect, since options do their work while `magyar.ldf` is being loaded;
- the buggy `varioref.sty` has been loaded as `\usepackage[magyar]{varioref}` – this happens until the patch is integrated to `varioref.sty`, the current version is so buggy that it displays an untracable L^AT_EX error each time the Hungarian language is activated (see in subsection 2.28).

3 Miscellaneous tricks

First we introduce some common expansion tool macros defined by L^AT_EX:

³ Of course, suffixes with only one form are not supported by `\told`.

```

\def\@empty{}
\long\def\@gobble#1{}
\long\def\@gobbletwo#1#2{}
\long\def\@firstofone#1{#1}
\long\def\@firstoftwo#1#2{#1}
\long\def\@secondoftwo#1#2{#2}

```

`\@firstofone` differs from `\@empty`, because it may not be followed by `}`, it ignores spaces in front of its argument, and it removes at most one pair of braces around its argument. All of these properties are consequences of the macro expansion rules described in chapter 20 of The \TeX book ([3]).

This section contains \TeX macro and typesetting tricks not tightly related to the Hungarian language.

3.1 The factorial sign in math mode

`nath.sty` contains a smartest definition of the factorial operator, so $(a+b)!/a!b!+c!\cdot d!$, with proper spacing can be typed as `$(a+b){!}/a!b!+c!\cdot d!$`. The only place where braces were needed is before the slash. `magyar.ldf` adapts the definition:

```

\def\factorial{\mathchar"5021\mathopen{}\mathinner{}}
\expandafter\addto\csname \expandafter\ifx
\csname mathoptions@on\endcsname\relax% detect nath.sty
check@mathfonts\else mathoptions@on\fi\endcsname{%
\catcode'\!12 \mathcode'\!8000
\begingroup\lccode'\!'\lowercase{\endgroup\def~}{\factorial}}

```

3.2 Including the structure name in references

Texts like “in subsection 5.6” are usually typed as `in subsection~\ref{that}`. But it would be nice if \LaTeX would be able to guess that the place `\ref{that}` points to is actually a subsection. The structure depth can be deduced by counting the dots in the reference: a subsection has one dot (in an article), and a subsubsection has two dots. `magyar.ldf` provides the `\refstruc` command which has a smarter detection scheme: it changes all roman and arabic numbers to one (1, i or I) in the reference, and compares the result with the tokens generated by `\thechapter`, `\thesection` etc., with `\c@chapter` etc. set to 1 temporarily. This should work in most cases, although it cannot refer to equations, tables or figures. In Hungarian text, the Hungarian structure names are emitted, and other texts the original, English control sequence names are printed. `\refstruc` supports the definite article and suffixes, so for example `\Az{\refstruc{that+tol}}` may emit “az 1. fejezettől” (meaning: from chapter 1).

The full implemenatation is quite long, and is not included here, but the macro that changes all roman and arabic numbers to one is presented:

```

\def\NumbersToOne#1{\nonumbers@a#1\hfuzz}
\def\nonumbers@skipa#1\nonumbers@s#{#1\nonumbers@a}
\def\nonumbers@a#1{% change first digit
  \ifx#1\hfuzz \expandafter\@gobble
  \else\if1<1\string#1\else\if\noexpand#1mi\else\if\noexpand#1di%
  \else\if\noexpand#1ci\else\if\noexpand#1li\else\if\noexpand#1xi%
  \else\if\noexpand#1vi\else\if\noexpand#1ii\else\if\noexpand#1MI%
  \else\if\noexpand#1DI\else\if\noexpand#1CI\else\if\noexpand#1LI%
  \else\if\noexpand#1XI\else\if\noexpand#1VI\else\if\noexpand#1II%
  \else\noexpand#1\nonumbers@skipa
  \fi\fi\fi\fi\fi\fi\fi \fi\fi\fi\fi\fi\fi\fi\fi\fi \nonumbers@s}
\def\nonumbers@s#1{% gobble next digits
  \ifx#1\hfuzz \expandafter\@gobble
  \else\if1<1\string#1\else\if\noexpand#1m\else\if\noexpand#1d%
  \else\if\noexpand#1c\else\if\noexpand#1l\else\if\noexpand#1x%
  \else\if\noexpand#1v\else\if\noexpand#1i\else\if\noexpand#1M%
  \else\if\noexpand#1D\else\if\noexpand#1C\else\if\noexpand#1L%
  \else\if\noexpand#1X\else\if\noexpand#1V\else\if\noexpand#1I%
  \else\noexpand#1\nonumbers@skipa
  \fi\fi\fi\fi\fi\fi\fi \fi\fi\fi\fi\fi\fi\fi\fi\fi \nonumbers@s}

```

3.3 Enabling long page numbers

If the width of a page number is longer than `\@pnumwidth` in the table of contents, L^AT_EX emits an “Overfull `\hbox`” warning. This can be got rid of by changing `\@dottedtocline` defined in the L^AT_EX kernel. The line

\hb@xt@{\pnumwidth}{\hfil\normalfont \normalcolor #5}%

should be changed to

```
\setbox\@tempboxa\hbox{\normalfont \normalcolor #5}%
\ifdim\wd\@tempboxa<\@pnumwidth\setbox\@tempboxa
\hbxt\@pnumwidth{\hfil\unhbox\@tempboxa}\fi
\box\@tempboxa
```

Although this change isn't related to the Hungarian language, `magyar.ldf` can be asked to do it with the `dottedtocline=` load option.

3.4 Removing AMS warnings from \listoftables

Some AMS document classes (such as `amsart.cls`) produce an “Overfull \hbox” warning for each line in the `\listoftables` and `\listoffigure`. This can be fixed by changing `\@tocline{0}{3pt plus 2pt}{0pt}{}{}{}` to `\@tocline{0}{3pt plus 2pt}{0pt}{}{\parindent}{}{}` in `\l@table` and `\l@figure` defined by the classes. The following code does the change:

```

\ifnum 0<%
  \expandafter\ifx\csname setTrue\endcsname\relax\else1\fi
  \expandafter\ifx\csname allowttyhyphens\endcsname\relax\else1\fi
\space
\def\amsfix#1#2#3#4#5#6#7\vfuzz{%
  \def\reserved@a{#6}%
  \ifx\tocline#2\ifx\reserved@a\@empty%
    \def#1{\@tocline{#3}{#4}{#5}{\parindent}{}}%
  \fi\fi}
\expandafter\amsfix\expandafter\l@table \l@table ,,,,,,\vfuzz
\expandafter\amsfix\expandafter\l@figure\l@figure,,,,,,\vfuzz
\fi

```

Control sequences `\setTrue` or `\allowttyhyphens` are defined by each of the AMS document classes, so their presence indicates that one of those classes are loaded. The logical or operation using `\ifxs` nested to the `\ifnum` test is also worth noting.

3.5 Conditionally discarding the rest of the file

The naïve solution `\ifskiprest\endinput¶\fi` yields the \TeX error message “end occurred when `\iftrue` in line n was incomplete” if there is a line break at the `¶` sign. Without the line break, the naïve solution works perfectly, because `\endinput` stops reading the current file *after* the current line, so the `\fi` also gets evaluated.

It is possible to do some action before `\endinput`:

```

\expandafter\ifx\csname ver@foo.sty\endcsname\relax
  \endinput \errmessage{I am incompatible with foo.sty}\fi

```

All the action above must be put after `\endinput` without a line break. The `\csname fi\endcsname` construct closes the `\ifx` when the condition is true, but is invisible when the condition is false, and \TeX is skipping tokens.

The `\@ifpackageloaded` macro of the \LaTeX kernel implements the conditional stop with a different trick. The following two constructs are equivalent: `\@ifpackageloaded{foo}{\endinput\errmessage{I am incompatible with foo.sty}}{}` and

```

\expandafter\ifx\csname ver@foo.sty\endcsname\relax
  \expandafter\@gobble
\else \expandafter\@firstoftwo \fi
{\endinput
\errmessage{I am incompatible with foo.sty}}

```

In the trick above, `\errmessage` isn’t in the same line as `\endinput`. This isn’t a problem, because by the time `\endinput` is evaluated by \TeX ’s stomach, `\errmessage` has been read from the file, and it is already on the input stack. `\endinput` doesn’t discard the input stack, it just prevents more lines to be read from the current file.

3.6 Typesetting text verbatim

`\catcodes` are assigned when \TeX 's eyes read the next character from the current line. Thus a `\catcode` command affects all subsequent characters of the current line, as well as the following lines. But once a category code has been assigned, it won't be affected by `\catcode` commands. For example, `\@firstofone{\catcode'A 14 AAA}` makes `A` a comment starter character, but it emits three `As`, because the category code of the three `As` has already been assigned by the time `\catcode` is evaluated. The reason why the `\verb` command of the \LaTeX kernel cannot be part of a macro argument is the same: `\verb` changes the `\catcode` of most characters to other, but these changes have no effect inside a macro argument, because the argument has been read from the input file by the time `\catcode` can take effect.

A verbatim macro can be based on the `\meaning` primitive instead of changing `\catcodes`, so this macro can be a part of macro arguments, but \TeX 's eyes has destroyed some information such as comments and the exact number of successive spaces by the time `\meaning` is expanded. For example, these definitions are from `binhex.dtx`:

```
\def\verbatimize#1{\begingroup
  \toks0{#1}\edef\next{\the\toks0}%
  \dimen0\the\fontdimen2\font \fontdimen2\font=0pt
  \expandafter\stripit \meaning\next
  \fontdimen2\font=\dimen0 \endgroup}
\def\next{}
\expandafter\def\expandafter\stripit\meaning\next{}
```

3.7 Stopping the iteration

Let's suppose we need a macro that capitalizes all "a" and "b" till the first "":

```
\def\ucab#1{%
  \if\noexpand#1.\expandafter\@gobble
  \else\if\noexpand#1aA%
  \else\if\noexpand#1bB%
  \else\noexpand#1%
  \fi\fi\fi\ucab}
\message{\ucab abc.abc} % -> ABcab
```

`\noexpand` prevents expansion of `#1` in case it is an expandable control sequence such as `\the` or a macro. If `\if` is changed to `\ifx`, then not only the character codes, but the category codes would be compared.

The trick that stops the iteration here is that `\expandafter` expands the first `\else` that will remove everything up to the last `\ucab`. Then comes `\@gobble`, which removes `\ucab`, thus the iteration is stopped.

The construct doesn't work when `#1` had braces around it, or it is `\if...`, `\else` or `\fi`. Also, spaces will be ignored because of macro expansion.

But what if we'd like to capitalize only the *first* “a” or “b”? Then we would need `\expandafter\expandafter\expandafter\@gobble` after “A”, and 7 `\expandafter`s after “B”. But `\expandafter` can be completely avoided using a different approach, based on macro arguments:

```
\def\helpif#1#2{#1\@firstoftwo}
\def\ucabs#1{%
  \if\noexpand#1.\helpif\fi\@secondoftwo{
    {\if\noexpand#1a\helpif\fi\@secondoftwo{A}
    {\if\noexpand#1b\helpif\fi\@secondoftwo{B}
    {\noexpand#1\ucabs}}}%
}\message{\ucabs cbbas} % -> cBbas
```

It is not possible to move `\fi` into the definition of `\helpif`, because then TeX won't see that `\fi` when it is skipping the whole `\if ... \helpif`. With a small rearrangement we can get rid of `\@secondoftwo`:

```
\@gobble{\iftrue\iftrue} % \def\helpjf... contains 2*\fi
\def\helpjf#1\fi{#1\expandafter\@firstoftwo
  \else\expandafter\@secondoftwo\fi}
\def\ucabj#1{%
  \helpjf\if\noexpand#1.\fi{
    {\helpjf\if\noexpand#1a\fi{A}
    {\helpjf\if\noexpand#1b\fi{B}
    {\noexpand#1\ucabs}}}%
}\message{\ucabj cdabs} % -> cdAbs
```

The line containing `\@gobble` above is needed so that `\def\helpjf` can be put inside `\iffalse ... \fi`, and TeX's `\fi` count won't decrease when seeing the two `\fi` tokens in the definition of `\helpjf`.

3.8 Appending tokens to a macro

TeX doesn't provide primitives for modifying the expansion text of a macro, but it is possible to define a new macro with the contents of the old one and some new tokens. For example, `\expandafter\def\expandafter\foo\expandafter{\foo\iffalse$}` appends the two tokens `\iffalse$` to the macro `\foo`. Three `\expandafter`s were used to make the old `\foo` only expanded once. None of the above tokens were expanded, fortunately. Any tokens can be appended this way, if they are nested with respect to braces. But care has to be taken with doubling `#`s:

```
\def\AppendTo#1#2{\expandafter\def\expandafter
  #1\expandafter{#1#2}}
\def\foo{ } \AppendTo\foo{#}
```

yields the TeX error “Illegal parameter number in definition of `\foo`”. This can be solved by using token list registers, who double their hashmarks when being expanded in an `\edef`:

```

\def\AppendTo#1#2{\begingroup
  \expandafter\toks\expandafter0\expandafter{\foo#2}%
  \global\edef#1{\the\toks0}\endgroup}
\def\foo{} \AppendTo\foo{#x}
\show\foo % \foo=macro:-> ##x

```

Note that `#s` has to be properly formulated when a macro is defined, and it is `\def` who eats half of `#s` (and converts `#1` etc. to special, inaccessible tokens), but `\edef` doesn't convert `#6` to special tokens if it comes from a token list register. The disadvantage of the second definition of `\AppendTo` that it must be `\global`. (In fact, there is a much longer solution that manually doubles the `#s`.) The `\addto` command of Babel and the `\vref@addto` command of `varioref.sty` are `\global`, similarly to this solution.

3.9 Processing arbitrary package options

L^AT_EX packages may use the standard commands `\DeclareOption`, `\ExecuteOption` and `\ProcessOptions` to access package options passed to them, and these commands work fine when there is a finite fixed set of options. The `\DeclareOption*` command can be used to declare arbitrary options:

```

%\DeclareOption{10pt}{\typeout{got ten-pt}} % (1)
\DeclareOption*{\typeout{got=(\CurrentOption)}}
\ProcessOptions % in file foo.sty

```

When that `foo.sty` is loaded as `\usepackage[,foo=bar,,no,]{foo}`, two lines will be printed: `got=(foo=bar)` and `got=no`. The optional argument of `\usepackage` may contain spaces and/or a single newline around commas and at the ends. Class options are passed to `\DeclareOption*`, so when `\documentclass[10pt]{article}` is active, `got=(10pt)` will not appear, but when line (1) is uncommented, `got ten-pt` will appear.

There is an alternative, low-level way for accessing all the options at once:

```

\AtEndOfPackage{\let\@unprocessedoptions\relax}% prevent warning
\typeout{\csname opt@\@currname.\@current\endcsname}

```

This prints the full of option lists with extra spaces and newlines removed, but commas, including superfluous ones, are kept intact.

4 Beyond the current magyar.ldf

4.1 Software related to Hungarian typesetting

Although `magyar.ldf` contains most of the functionality needed for following the Hungarian typographic traditions, there are more utilities and packages that help typesetting Hungarian texts. Most of these software, including `magyar.ldf` is going to be available under the name MagyarL^AT_EX from the URL <http://www.math.bme.hu/latex/>.

- magyar.ldf** The new Hungarian module for **Babel**. Version 1.5 was written by Péter Szabó from the autumn of 2003.
- huhyph.tex** or **huhyph3.tex** The old (version 3) Hungarian hyphenation **\patterns** for the T1 encoding, written by Gyula Mayer in 1998. Part of most **T_EX** distributions. See more information in subsection 2.1.
- huhyphc.tex** The new version of the Hungarian hyphenation **\patterns** for the T1 encoding, written by Gyula Mayer in 2002 ([4]). Part of most **T_EX** distributions. Hyphenates foreign compound words on the subword boundary, e.g. “szin-kron”. See more information in subsection 2.1.
- huhyphf.tex** The new version of the Hungarian hyphenation **\patterns** for the T1 encoding, written by Gyula Mayer in 2002 ([4]). Part of most **T_EX** distributions. Hyphenates foreign compound words phonetically, e.g. “szink-ron”. See more information in subsection 2.1.
- lafmtgen.pl** An easy-to-use Perl script that can generate format files (**.fmt**) containing all hyphenation patterns required by the specified **L^AT_EX** document. Has some other features related to generating and installing format files. To be used with the UNIX **te_EX** distribution. It was written by Péter Szabó in 2003.
- huplain.bst** Bib_T**E**X style file for Hungarian bibliographies, based on **plain.bst**. It encourages sharing the same **.bib** database between Hungarian and English documents. It follows the (simple) convention that the style of a bibliography depends on the language of the document containing the entry, not the language of the entry itself. It was written by Péter Szabó in 2003.
- husort.pl** A drop-in replacement of **makeindex** that follows the Hungarian standards of index sorting and typesetting. It is implemented as a Perl script. It was written by Péter Szabó in 2003.
- ccs.extract.pl** A Perl script that helps hyphenation of words containing long double Hungarian consonants. It finds all occurrences of such words in the document and lets the user decide whether to insert **magyar.ldf** shorthands for **\discretionary** breaks for long double consonants in each unique word. The program was written by Péter Szabó in 2003.
- magyar.xdy** Hungarian style file for the **Xindy** index processing program. Implements the Hungarian sorting order and a Hungarian typesetting style. The implemented sorting order does not follow Hungarian rules as strictly and advancedly as **husort.pl**. It was written by Péter Szabó in 2003.
- CM-Super** The EC fonts in Type 1 format in T1 and various other encodings. It is not part of **MagyarL^AT_EX**, but it is available from CTAN. It is useful for converting Hungarian text to PDF, so the generated PDF file will contain the EC fonts in Type 1 format, and will be rendered quickly and nicely by Acrobat Reader.
- MagyarISpell** The Hungarian language database of the **ISpell** spell checker for UNIX. On Debian systems it can be installed with the command **apt-get install ihungarian**. **ISpell** has a **T_EX** mode, which skips control sequences and comments when checking **T_EX** source. (Unfortunately, the arguments of **\begin{tabular}** and many other non-textual elements of **L^AT_EX** documents are not skipped.) **ISpell** can be used interactively, but this method is

not comfortable, and incremental checking is not possible. **ISpell** has an interprocess communication protocol, through which it can be integrated into text editors. For example, **Emacs** has built-in **ISpell** support, which can mark incorrect words visually. **OpenOffice**, **LyX**, editors in **KDE** and newer versions of **Vim** can also use **ISpell** for spell checking. **MagyarISpell** works fine in these editors. It is not part of **MagyarLaTeX**, but it is available for free.

Note, however, that both the database and the stemmer of **MagyarISpell** is far from perfect, but among the Hungarian spell checkers only this one works inside **ISpell**, so only this can be easily integrated into editors.

MSpell A commercial Hungarian spell checker with free Linux download, developed by Morphologic (a company in Hungary that produces linguistic software). Doesn't have an interactive mode, but can replace **ISpell** in interprocess communication mode. A shell script is provided that replaces the **ispell** command, so **MSpell** can be integrated into text editors more easily. It is not part of **MagyarLaTeX**.

HuSpell The successor of **MagyarISpell**, based on a different spell checking architecture. It understands Hungarian much better than **MagyarISpell**, but since it is not based on **ISpell**, it is harder to integrate into text editors. For example, it is not available from the **Emacs** spell checking menu, even if it is installed. It is not part of **MagyarLaTeX**, but it is freely available.

4.2 Future work

Some features are still missing from **magyar.ldf**: **letter.cls** is not customized properly, the left indentation of the nested list environments is also not customized; a macro that emits numbers with groups of three digits separated is missing; **layout.sty** and many other packages don't have Hungarian captions yet; the shorthand ' is not disabled in math mode to give a chance to **nath.sty** to typeset H_{symm} with $\$H_{\text{'symm}}\$$; **\hunnewlabel** should store **table**, **figure** or **equation**, so **\refstruc** should insert it; new fonts and/or methods should be developed in place of **'tty**; Hungarian typography needs a baseline grid, which is almost impossible to enforce in **LaTeX**; some proposed separation symbols after the **\paragraph** are not available yet; section titles should not be larger than normal text; bold fonts should be substituted for bold extended fonts, whenever available – and never with an error or warning message; page numbers should be removed from blank pages; the width of **\parindent** should be computed based on **\textwidth**; the length of the last line of a paragraph should not be too near to the right margin, especially if **\parindent = 0**; **\vskips** above and below sections should be reduced; **\MathReal** should be extended with physical units; providing the commands **\H** and **\.** for OT1-encoded typewriter fonts; virtual fonts to support **\umlautlow** in T1 encoding; boldface in **\begin{description}** should be changed to **\emph**; changing the values of some compile-time options in run-time; the **\textqq** command should work both as a command and an environment; **\told** should generate suffixes for month names.

Other features should be implemented outside **magyar.ldf**, as external programs. All of the programs in subsection 4.1 needs improvements in some way.

4.3 Conclusion

An update `magyar.ldf` that follows the Hungarian typographical rules and works together with the most popular \LaTeX packages without problems, has been awaited for many years. This new version is ready, as a single file longer than anything else ever before, and it is filled with many advanced features. Most of the features adapt \LaTeX to the Hungarian typographical rules, but some of them are just bugfixes to various external packages, including fixes to design flaws and compatibility issues in `Babel` itself. The implementation of some features clearly show that \TeX macro programming is an obscure and ineffective way of solving some of the language-related problems. It is hoped that new versions of Ω , together with the new version of `Babel` will provide a framework in which such problems can be addressed compactly and elegantly, without the awareness of actual and possible compatibility glitches.
